

# VLSI ENACTMENT OF AES FOR IOT APPLICATIONS

**K.R. ANUSHA HINDUJA**

Assistant professor, Department of ECE

Mina institute of Engineering and Technology for Women, Miryalaguda, TS.

**Abstract:** Cryptography techniques are considered secure and efficient algorithms. Despite that like other symmetric encryption algorithms, the secret key distribution is still considered as a critical issue. Again, to encrypt or decrypt a single block (128-bit) of data, an essential amount of computational processing has to be done which consumes more power. Internet of things (IoT) is the extension of the Internet to connect just about everything on the planet. This paper presents implementation of data security algorithm based on Nano- AES or lightweight cryptography with 256 bit key for IOT application. A new one-dimensional substitution Box (S-box) is proposed instead of conventional 2-D S-box and previous 1-D S-box. Simulated result shows that proposed Nano-AES lightweight cryptography gives better performance than previous in term of delay, throughput, transmission time, efficiency rate.

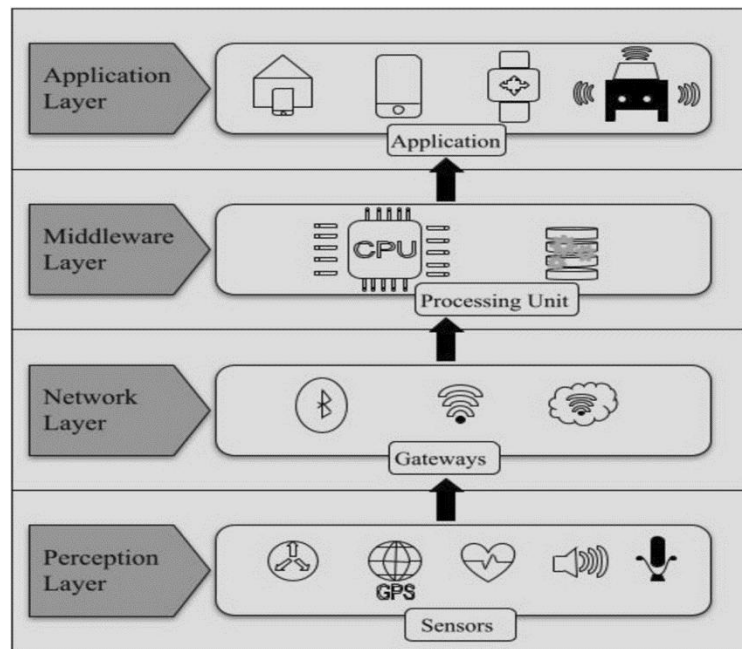

**Keywords—Nano-AES    lightweight    Cryptography,    Encryption,    Decryption.**

## I. INTRODUCTION

Nano-AES is a lightweight implementation of the Advanced Encryption Standard (AES) algorithm. It is designed for resource-constrained devices, such as those used in the Internet of Things (IoT). Nano-AES is optimized for area and power consumption, while still providing a high level of security. The Nano-AES algorithm is based on the original AES algorithm, but it has been simplified and optimized for smaller devices. Cryptography in recent years with the advancement of VLSI has led to its implementation of Encryption and Decryption techniques, where the process of translating and converting plaintext into cipher text and vice versa is made possible.

The Nano-AES lightweight Encryption Algorithm (NA- LEA) is a 128-bit block cipher developed by South Korea in 2013 to provide confidentiality in high-speed environments such as big data and cloud computing, as well as Nano-AES lightweight environments such as IoT devices and mobile devices. LEA has three different key lengths: 128, 192, and 256 bits. LEA

encrypts data about 1.5 to 2 times faster than AES, the most widely used block cipher in various software environments.

**Fig 1 Example of Nano-AES lightweight cryptography applications**

LEA is one of the cryptographic algorithms approved by the Korean Cryptographic Module Validation Program (KCMVP) and is the national standard of Republic of Korea (KS X 3246). The block cipher LEA consisting of ARX operations, bitwise Rotation, and bitwise XOR for 32-bit words processes data blocks of 128 bits and has three different key lengths: 128, 192, and 256 bits. LEA with a 128-bit key, LEA with a 192-bit key, and LEA with a 256-bit key are referred to as “LEA-128”, “LEA-192”, and “LEA-256”, respectively. The number of rounds is 24 for LEA-128, 28 for LEA-192, and 32 for LEA-256.

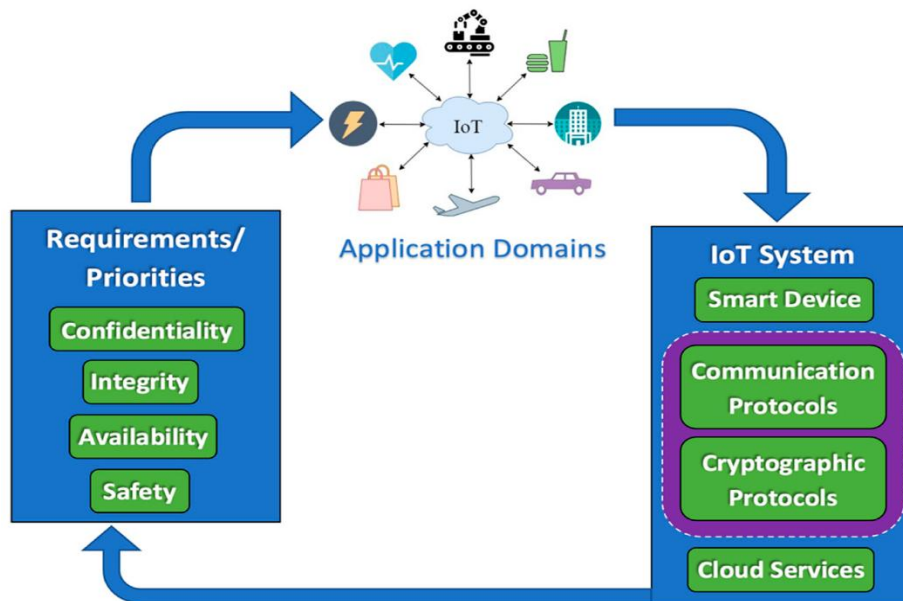

LEA has very good performance in a general-purpose software environment. In particular, it is possible to encrypt at a rate of about 1.5 to 2 times on average, compared to AES, the most widely used block cipher in various software environments. The tables below compare the performance of LEA and AES using FELICS (Fair Evaluation of Nano-AES lightweight Cryptographic Systems),[3] a benchmarking framework for evaluation of software implementations of Nano-AES lightweight cryptographic primitives. Encryption is already applied as standard on the data link layer of communication systems such as the cell phone. Even in such a case, encryption in the application layer is effective in providing end-to-end data protection from the device to the server and to ensure security independently from the communication system (Fig. 1). Then encryption

must be applied at the processor processing the application and on unused resources and hence should desirably be as Nano-AES lightweight as possible.

The biggest security-related threat of IoT systems from the traditional IT systems is that even using devices for data collection from the real world can become a target of cyberattacks. For example, the purpose of applying IoT to a plant is to significantly improve the productivity and maintainability by collecting data from a large number of sensors installed in production equipment, by analysing it and performing autonomous control in real time. If sensor data should be falsified during this process, incorrect analysis results would be induced and erroneous control would result due to such an occurrence having the potential of leading to major damage. Moreover, since measurement data and control commands are trade secrets associated with the know-how of production and management, preventing leakages is also important from the viewpoint of competitiveness. Even if there is no problem at present, it is necessary to consider the effect of threats that might become evident in the future.

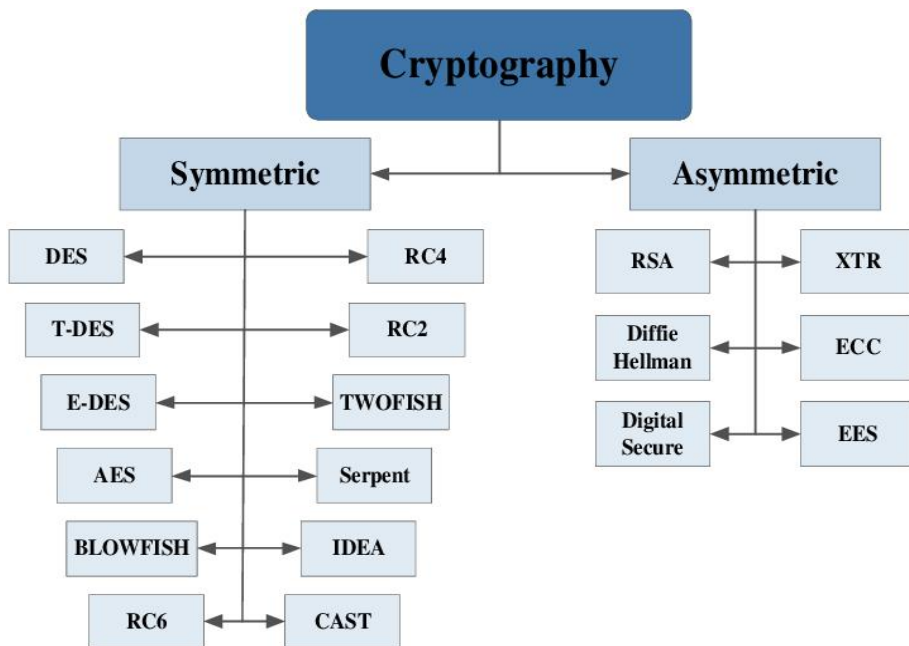

## **II. PROPOSED METHODOLOGY**

Cryptographic algorithms can be either symmetric or non- symmetric. Symmetric Cryptographic algorithms are those in which we use the same set of keys both at the transmitting end as well as the receiving end. AES is a symmetric block cipher. AES Algorithm may be used with the three different key lengths of 128,192 and 256. AES is referred to as “AES- 128”, “AES-192”, and “AES-256” accordingly. In the proposed work we have used AES-128. Thus, symmetric cipher requires a single key for both encryption and decryption, which is independent of the plaintext and the cipher itself. Hence, it would be impractical to retrieve the plaintext solely based on the cipher text and the decryption algorithm, without knowing the encryption key. Thus, the secrecy of the encryption key is of high importance in symmetric ciphers such as AES.

**Fig 2 Proposed Block diagram**

AES can process data blocks of 128 bits, using cipher keys with lengths of 128, 192, or 256 bits. In the proposed work, the key length is 128 bits. Rijndael was designed to handle additional block sizes and key lengths, and however they are not adopted in this standard. The Advanced Encryption Standard (AES) specifies a FIPS-approved cryptographic algorithm that can be used to protect electronic data. Encryption converts data to an unintelligible form called ciphertext; decrypting the ciphertext converts the data back into its original form, called plaintext. The 128 bit data block is divided into 16 bytes. These bytes are mapped to a 4×4 array called the state and all the internal operation can be performed on state. Internally, the AES algorithm’s operations are performed on a two-dimensional array of bytes called the State. The encryption process includes the following transformations of states: SubBytes(), ShiftRows(), MixColumns(), and AddRoundKey(). The encryption process also includes a key schedule. The AES algorithm takes the Cipher Key, K, and performs a Key Expansion routine to generate a key schedule. In the decryption process, the Cipher transformations are inverted and then implemented in reverse order to produce a straightforward Inverse Cipher for the AES algorithm. The individual transformations used in the Inverse Cipher are InvShiftRows(), InvSubBytes(), InvMixColumns(), and AddRoundKey() . The decryption process also includes a key schedule similar to Encryption process.

**Fig 3 Cryptography stages**

In this work, we have implemented WiMax/IOT Security using Nano-AES lightweight cryptography Cryptographic Algorithm. It is designed WiMax MAES Security Algorithm sub-module, both at the Encryption and Decryption end, based on the internal operations of the algorithm, as mentioned above. Each sub-module is designed, simulates and synthesized step by step as per algorithm. The results of simulation and synthesis are presented separately.

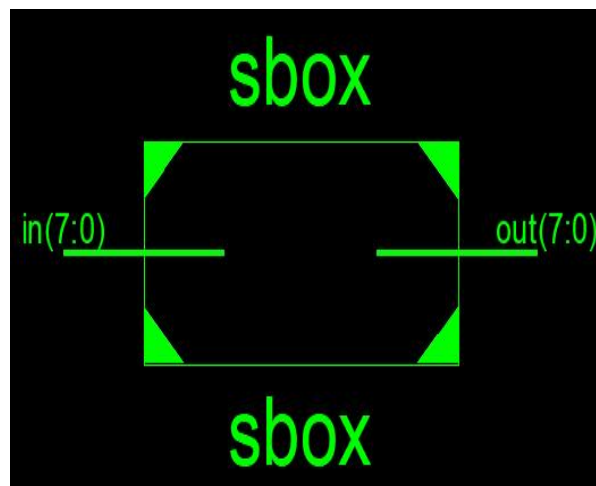

### III. SIMULATION AND RESULTS

The designed WiMax/IOT MAES Security Algorithm implementation has multiple sub-modules inside it both at the Encryption and Decryption end, based on the internal operations of the algorithm. Top module is designed, simulated and synthesized as per proposed algorithm. First, we are presenting the results of simulation.

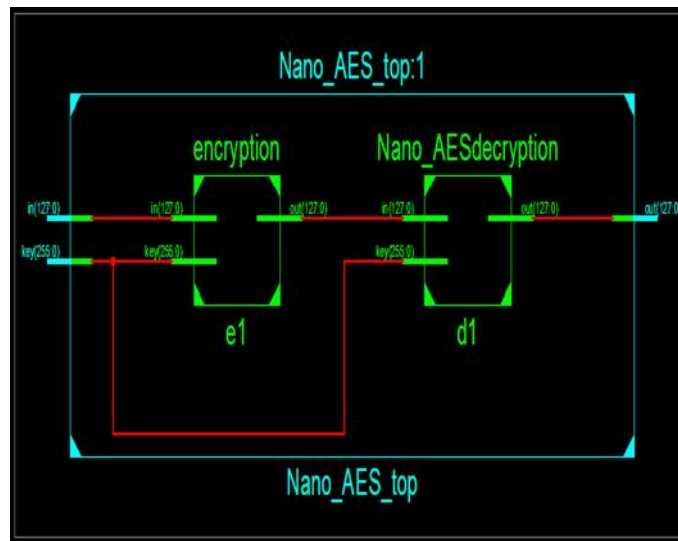

**Fig 4 Top View**

In figure 4, top view of proposed Nano-AES lightweight cryptography algorithm, where 128 bit input, 128 bit output and 256 Encryption and 256 Decryption key taken.

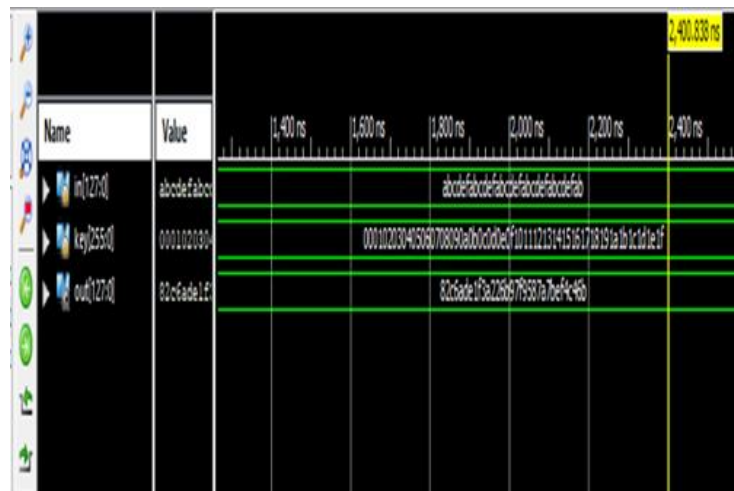

**Fig 5 Top module of proposed 1D S-box**

Figure 5 is showing the top module of the proposed 1 dimensional sub-byte box. Here 8bit input is giving to the Sbox and its generating 8 bit output after operation of s- box.

**Fig 6 RTL view of Encryption and Decryption Process**

The figure 6 is showing the RTL view of encryption and decryption process. The 128-bit input data is encrypted by the 256-bit key and at the output side it is decrypted by same 256 bit key and original data is recovered.

**Fig 7 Encryption process**

Figure 7 presents the encryption process of the proposed Nano-AES lightweight cryptography algorithm.

**Comparison Table**

Sr No.	Parameters	Previous Result [1]	Proposed Result
1	Input bit	80	128
2	Frequency	10 MHz	23 MHz

3	Area	28860.580	13017
4	Total Power	0.2535 mW	0.18mW
5	Throughput	250 Mbps	2949 Mbps
6	Delay or Latency	100 ns	43.398ns

#### **IV. CONCLUSION**

This paper presents implementation of data security algorithm based on Nano-AES lightweight cryptography with 256 bit key for IOT application. It is developed for the implementation of both encryption and decryption process. The preceding work was based on an input of 80 bits of data, however the suggested work is going to be based on an input of 128 bits of data and 256 bits of key, which will give a higher level of security. In the work that is being suggested, the value of frequency is set at 23 MHz, while in the work that was done before, it was set at 10 MHz. The overall throughput of the proposed job is 2949 Mbps, while the current work only achieves 250 Mbps, and the overall latency of the proposed work is 43.39 ns, whereas it was 100 ns in the previous work.
